I. Introduction

Enrollment is a critical process for students in higher education. While most schools use Academic Information Management Systems (AIMS) to manage student records and subjects, the enrollment process is often still confusing and slow. Students with outstanding balances cannot enroll online due to school rules, forcing them to line up physically. This results in long queues, delays, and stress for both students and staff.

This study proposes a rule-based enrollment workflow and queue management system that guides students step by step, manages queues digitally, and shows real-time enrollment status — all without changing school policies or replacing AIMS.

II. Objectives of the Study

II.1. General Objective

To develop a rule-based enrollment workflow and queue management system that improves efficiency and transparency while following school rules.

II.2. Specific Objective

- Provide real-time queue management for enrollment transactions.
- Give step-by-step instructions based on each student's situation.
- Track enrollment status in real time.
- Improve coordination between Finance and Registrar offices.
- Generate reports for bottleneck identification and workflow improvement.

III. Scope of the Study

This study focuses on developing a rule-based enrollment workflow and digital queue management system that complements the existing Academic Information Management System (AIMS). The system is designed to assist students in completing enrollment efficiently, provide clear guidance based on their specific situations, and help administrative staff manage queues and monitor progress in real time. The scope emphasizes improving the

enrollment experience without altering school policies or replacing existing systems.

The study covers the following key areas:

1. The system supports enrollment in one department or college.
2. Handles three scenarios: students with no balance, with outstanding balance, and with academic issues.
3. Provides digital queue management, step-by-step guidance, and real-time status tracking.
4. Generates basic reports for administrative use.
5. Simulates integration with AIMS using sample data.

Limitations:

1. Does not replace or modify AIMS.
2. Does not handle real payments or financial transactions.
3. Limited to prototype environment; real student records are not used.
4. Students must follow instructions for the system to work efficiently.
5. Web-based only; no physical hardware.

IV. Significance of Study

Students:

The system helps students by providing clear instructions based on their enrollment situation. It reduces waiting time, prevents confusion, and makes the enrollment process faster and more organized.

Registrar and Finance Offices:

Staff can manage student queues more efficiently, track real-time progress, and reduce repetitive questions. This makes enrollment less stressful and more structured for both staff and students.

School Administration:

The system provides reports that show enrollment bottlenecks and peak periods. This helps administrators make better decisions, improve resource allocation, and plan enrollment periods more effectively.

Future Researchers:

This study can serve as a reference for workflow optimization and queue management in educational institutions. Future researchers may expand it to other administrative processes.
